Workshop 5: Phylogenies & Molecular Clock

Daniel Jeffares

2025-11-17

Table of contents

1 Learning objectives	2
2 Introduction	3
2.1 Phylogenetic trees and the molecular clock	3
2.2 The molecular clock and the real world	3
3 Exercises	3
3.1 Obtaining data	4
3.2 Visualising and analysing data	4
3.3 Starting analysis in Mega	4
3.4 Group the strains by year.	6
3.5 Building a phylogenetic tree	8
3.5.1 Understanding the tree	10
3.6 Measuring molecular change over time	10
3.7 Analysis of genetic change with time	13
3.7.1 Set up the script	13
3.7.2 Loading and plotting the data	14
3.7.3 Interpret the data	15
3.8 Optional: Does the influenza virus spread across the Tasman Sea?	15
3.9 Interpreting the Tasman sea data	17
4 Summary: what we have learned	17
5 Exam style questions	18
5.1 Question 1 (10 points)	18
5.2 Question 2 (10 points)	18

! Important

We do not advise doing this workshop on a Mac since Mega software does not work very well on the Mac OS. It is best to use the University PCs which have the software already installed.

1 Learning objectives

The aim of this practical is to learn to visualise and interpret the data using phylogenetic analyses. You will see that we can extract a lot of information about evolutionary processes and populations from a phylogeny.

By the end of this workshop, you should be able to:

- Build phylogenetic trees using MEGA software
- Infer evolutionary relationships based on phylogeny
- Correlate molecular evolutionary changes with time using R

i Glossary

Technical definitions for this workshop.

- **molecular clock:** The observation that mutations accumulate at a roughly constant rate over time.
- **node** (of a phylogenetic tree): A point where branches split, representing either a common ancestor (internal node) or a modern species (terminal node).
- **branch** (of a phylogenetic tree): A line connecting nodes, representing an evolutionary lineage. Branch length indicates the amount of evolutionary change. Due to the molecular clock hypothesis, branch lengths can be proportional to time.
- **mutation rate:** The frequency at which genetic changes occur in DNA over time, typically measured as substitutions per site per year.
- **purifying selection:** Natural selection that removes harmful mutations from a population, acting to preserve functional DNA sequences.

2 Introduction

2.1 Phylogenetic trees and the molecular clock

Much of what we can infer from phylogenies uses the model of the ‘molecular clock’. This is the observation that there tends to be a uniform, ‘clock-like’ rate of genetic change per year both *within* and *between* species. The *rate* of change differs between very different species and between genes.

Rates of change between species differ because:

- small organisms (like viruses and bacteria) have short generation times
- small organisms have high mutation rates

Rates of change between genes within a genome differ because the amount of *purifying selection* acting on a gene differs.

You can refresh your knowledge of Phylogenetic trees and the molecular clock from these two recordings:

- [Phylogenies and molecular clock Part 1](#)
- [Phylogenies and molecular clock Part 2](#)

2.2 The molecular clock and the real world

Evolutionary thinking can also help us to understand disease. For example, the global pandemic of the coronavirus SARS-CoV2 (which causes COVID-19 disease) is an RNA virus. As with all viruses, SARS-CoV2 is constantly undergoing evolutionary change.

The initial outbreak of the SARS-CoV2 virus in Wuhan China, was dated with amazing accuracy (to the month) to August 2019 [using a time tree](#). Being able to tell when outbreaks occur, as well as where, can be a very powerful tool as it can supplement what we can see from epidemiology. Analysis of DNA sequences is the only way we can obtain this information.

3 Exercises

In this workshop, we will study the evolution of the influenza virus. Influenza is an RNA virus that causes seasonal epidemics and occasional pandemics in humans. The influenza virus evolves very rapidly, which is why we need a new flu vaccine every year.

3.1 Obtaining data

There is a wealth of freely available sequence data available on GenBank. The downside is that most data is often poorly annotated and misses the critical associated information (e.g. date and place of collection). Here we will take advantage of the [influenza virus resource database](#), which is relatively well curated.

We have downloaded all the human full-length H3N2 type sequences from the hemagglutinin (HA) sequences from Wellington (New Zealand). Hemagglutinin (HA) a glycoprotein gene that is on the influenza virus surface.

You can [download the file H3N2_wellington.fasta here](#). This file has HA sequences from 72 influenza strains from 1985 to 2005. Sequences are already aligned, and sorted by date.

3.2 Visualising and analysing data

3.3 Starting analysis in Mega

We will use the Mega software for all analyses. It should be installed on your computers. If you would like to use your own computer, you can download it from [the mega website](#). Use the latest version, Mega 11.

! Important

Mega software does not work very well on the Mac OS.

Once you start Mega, you will see the following window. Be careful here, because Mega has multiple windows.

Next, load the H3N2_Wellington_seq.fa file through the Data > Open a File/Session Menu (Ctrl+O).

Then click:

- Analyze (not align)
- OK to Nucleotide Sequences
- Yes to Protein-coding nucleotide sequence data
- OK to Standard Genetic Code.

You should see the window shown below

3.4 Group the strains by year.

Click on the TA window at top left to see the Sequence Data Explorer.

You can scroll around and resize this window. This data file comprises 72 complete HA sequences from influenza H3N2 sampled between 1985 to 2005.

Now let's group the strains by year. This will be fairly easy because we sorted the data by year before we downloaded it. Samples have the year embedded in the name.

For example:

- this one is from 1985: Influenza A virus (A/Wellington/4/1985(H3N2))
- and this from 2004: Influenza A virus (A/Wellington/34/2004(H3N2))

First, go to the Display menu, and click on Show Group Names. This will help you to keep track of what you've done.

To group strains, select one or more strains from a year by clicking on the name of the first strain in the grey part of the window, and shift+click to select the last one, as below:

Then, go to the **Edit** menu, and click on **Create Group from Selection**. A new group will appear in the left-hand panel. Rename it to the year of sampling (e.g. 1985).

Repeat this for all years from 1985 to 2005.

3.5 Building a phylogenetic tree

As you will have seen, there are a large number of possible options for analysis in MEGA. However, we will build one tree along a single, robust methodology.

Go to the Phylogeny menu on the main menu:

Phylogeny → Construct/Test Neighbor-Joining

Choose these options:

- For Model/Method, choose the Kimura 2-parameter model of evolution
- For Test of Phylogeny, choose Bootstrap method and select 1000 bootstraps.
- Leave all other options as default

Then click OK.

Bootstraps represent statistical support for individual clades, values in excess of 70-80% are considered well supported.

After less than a minute, you will get a phylogenetic tree, a new Mega window.

It does not look very informative, so change the presentation of the tree using the menus on the left:

- First, deselect **Taxon Names**
- Under Layout, select **Auto-size tree**
- Define a root. The branch leading to the sequence from 1985 makes a biologically reasonable root. To define a root, simply right click with your mouse on the chosen branch and select **Place root**.
- You may also need to click toggle **Scaling** of the tree in the **Layout** menu.

You should see a tree like the one shown below.

3.5.1 Understanding the tree

What do you notice about the clustering of years on this phylogeny?

- In particular, look at the branch lengths (ie: genetic distance) from the root of the tree, to the tips.
- This indicates how many mutations have occurred since the common ancestor.

3.6 Measuring molecular change over time

An important question in phylogenetics is whether the accumulation of mutation (substitution rate) is constant over time. One way to test for this would be to count the number of mutations

from the root to each tip. Estimating the most likely root is not completely straightforward and counting the number of mutations from root to tip would require some scripting well beyond the scope of this practical. However, we can test whether genetic distances increase linearly with time.

To address the issue of linearity between substitution rates and time, we can first compute genetic distances between the sequences grouped by years. To do this:

- Go to the Distance menu (at the top of the main Mega window)
- Click Compute Between Group Mean Distance (see image below)
- Keep the Kimura 2 parameter model
- Click OK

You should see the matrix shown below.

Next, export this data to a file:

- In the matrix window, click on the **File** menu
- Then **Export/Print Distances**
- Output format: **text**
- Export Type: **column**

You should see a window something like the image below.

```

1985 1989 0.01817-
1985 1990 0.02176-
1989 1990 0.01049-
1985 1993 0.03154-
1989 1993 0.02064-
1990 1993 0.01587-
1985 1994 0.03220-
1989 1994 0.02248-
1990 1994 0.01768-
1993 1994 0.00638-
1985 1996 0.04226-
1989 1996 0.03233-
1990 1996 0.02681-
1993 1996 0.01823-
1994 1996 0.01994-
1985 2000 0.05988-
1989 2000 0.04978-
1990 2000 0.04470-
1993 2000 0.03745-
1994 2000 0.03973-

1989 2001 0.05106-
1990 2001 0.04628-
1993 2001 0.03901-
1994 2001 0.04130-
1996 2001 0.03182-
2000 2001 0.01669-
1985 2002 0.06407-
1989 2002 0.05321-
1990 2002 0.04972-

```

Finally edit and save this file: - Remove all the text above Species1 Species2 Distance - Remove the text below the data table, “Table. Estimates of Evolutionary Divergence over Sequence ...” etc

- Edit the Species1 Species2 Distance text to date1 date2 Distance
- Choose File > Save As
- Name the file H3N2_wellington.distances.txt

You can also [obtain a copy of this file here](#).

3.7 Analysis of genetic change with time

The remainder of this part of the workshop will use R Studio, so start RStudio now.

All the commands you'll need are in the R Script BI000056I-influenza-practical-2024.R, which is [available to download here](#).

Or you can create your own script, and copy the commands from here as we go along.

3.7.1 Set up the script

First, set up your script:

```
#BI000056I Influenza Virus Practical ----

# SET UP ----

#set your working directory
#Your working directory will be different!
setwd("~/path/to/your/files/")

#You can use the Session menu to set this with:
#Session menu > Set Working Directory > Choose Directory
#then select the directory where your files are.

#load the tidyverse
library(tidyverse)
```

3.7.2 Loading and plotting the data

Then load the Wellington data, and make a plot

```
# WELLINGTON DATA ----

#open your distances file, into a data frame:
#Your distance file may have a different name
flu <- as_tibble(read.table("H3N2_wellington.distances.txt", h=T))

#calculate how many years between two groups
flu$time.passed <- flu$date2 - flu$date1

#see if distance increases with time, as mutations accumulate
#make the plot
flu_plot<-ggplot(flu,aes(x=time.passed, y= Distance))+
  geom_point()+
  xlab("time distance between groups (years)")+
  ylab("genetic distance between groups")+
  theme_classic()

#view the plot
```

```

flu_plot

#now add a line of best fit:
flu_plot +
  geom_smooth(method="lm")

#examine whether the correlation is statistically significant:
cor.test(flu$time.passed,flu$Distance)

```

3.7.3 Interpret the data

You should see a good correlation between genetic distance and time distance.

- What causes this? (which process of evolution)
- Why is there such a strong correlation?

We can observe this relationship over just a few decades? - What does this tell us about the rate of change?

3.8 Optional: Does the influenza virus spread across the Tasman Sea?

Another use of virus genetic data is to determine how fast pathogens spread. Here, we'll show an example, where we examine whether people in New Zealand share the same strains as their neighbors in Australia across the Tasman Sea.

We have downloaded and aligned 118 strains from Australia and New Zealand. You can download the file [H3N2_tasman.fasta here](#). These sequences are already aligned

Then open MEGA, selecting **Analyse**, and

- Select the Distance menu, and Compute Pairwise Distances.
- You will see a matrix of distances
- In this window, select the **File** menu, and:
 - Export/Print Distances
 - Output format: CSV
 - Export type: Column

As before remove all the text above and below the data:

Above:

- Title: fasta file
- Description:

Below:

- Table. Estimates of Evolutionary Divergence between Sequences
- The number of base substitutions per site from between sequences are shown.

Then edit the header line to be: `region1 region2 Distance`, ensuring there is a space character between each column names.

Finally, save the file as `H3N2_tasman.distances.csv`.

You can also obtain [a copy of the H3N2_tasman.distances.csv file here](#).

Then examine the between-country differences and compare these to within-country differences, using the code in the R script, as below:

```
# TASMAN SEA DATA ----

#open the Tasman genetic distance data
tas <- read_csv("H3N2_tasman.distances.csv")

#add country1 and country2 columns
tas$country1 <- NA
tas$country2 <- NA

#label the countries using grep
tas[grep("NZ", tas$region1),]$country1 = "NZ"
tas[grep("AUS", tas$region1),]$country1 = "AUS"

tas[grep("NZ", tas$region2),]$country2 = "NZ"
tas[grep("AUS", tas$region2),]$country2 = "AUS"

#add a comparison.type column
tas$comparison.type <- NA

#mark the within country data
tas[which(tas$region1 == tas$region2),]$comparison.type <- 'within country'

#mark the between country data
tas[which(tas$region1 != tas$region2),]$comparison.type <- 'between country'
```

Now we make some plots:

```

#plot this data
#to examine whether genetic distances differ
#within a country vs between countries
ggplot(tas,aes(y=Distance,x=comparison.type))+ 
  geom_boxplot()+
  xlab("genetic distance comparison")+
  ylab("genetic distance")

#test whether there is any significant difference
#between the Distance within vs between countries
wilcox.test(Distance ~ comparison.type, data = tas)

#Now go back to the exercises, to think about this data.

# END ---

```

3.9 Interpreting the Tasman sea data

- Do genetic distances differ very much within vs between countries in the box plot?
- What would you expect to see if there was one lineage of influenza viruses circulating in Australia and another lineage circulating only in New Zealand?
- What would you expect to see if influenza viruses were spread freely between Australia and New Zealand?

4 Summary: what we have learned

- Phylogenetic trees can be used to visualise much more than merely evolutionary relationships between species
- We used the phylogenetic tree to examine whether mutation accumulation in the influenza virus is clock-like
- There seems to be a considerable amounts of evolutionary change occurring within the influenza viruses over just a few decades
- This change is approximately clock-like, with a roughly constant rate of mutation accumulation over time
- We can answer other questions about the spread of viruses using genetic data, such as whether influenza viruses spread freely between one place (Australia) and another (New Zealand)

5 Exam style questions

5.1 Question 1 (10 points)

How could we use the molecular clock to understand the spread of a plant pathogenic virus? In this scenario, we have access to infected crops from throughout the United Kingdom, sampled from different fields over a period of 10 years, and if we invest more funds we can access samples from up to 30 years ago. We are interested to know how to control the virus.

In your answer, explain:

- What *useful* information we could gather from the phylogeny and molecular clock analyses? (4 points)
- How we would collect samples so that we could obtain this information? (4 points)
- What analysis we would perform? (2 points)

5.2 Question 2 (10 points)

Evidence and implications of the molecular clock (10 points)

- What aspects of RNA viruses make them so suitable for observing the molecular clock? (3 points)
- Give an example of another situation in a multicellular species (plant, animal or fungi), where we might be able to observe the molecular clock over a longer period of time (e.g. decades, or centuries). (5 points)
- Now consider the genetic change between the multicellular species, once they have been diverging for millions of years. Assuming that you showed the genetic change was clock-like, what does this tell you about the effects of mutations? (2 points)
